

# Stellar Populations at Low-Metallicity via Nearby Star-Forming Galaxies

Peter Senchyna

Dan Stark

March 2016

Reionization Epoch

Aspen Center for Physics

image: NASA, ESA, and A. Aloisi (STScI)

$z=7.045$

$z=7.73$

Stark+2015, MNRAS 454, 1393

Stark+2016 (in-prep)

CIII], CIV at  $z \sim 6-7$ :  
what is producing this ionizing flux?

we need:

- more data at  
low metallicity

- constraints on  
HeII, CIV

# Cycle 23 HST/COS program (PI: Stark)

Hell emitters from  
Shirazi+Brinchmann 2012

$5.5 < \log M^* < 8.5$   
 $\log (\text{Hell}/\text{H}\beta) \sim -2$   
6 without WR bumps in SDSS

extreme tail of star-forming galaxies

Shirazi+Brinchmann 2012,  
MNRAS 421, 1043

WR signatures often absent in the optical at  
low-metallicity

## COS data provides:

key nebular emission lines

- CIII], HeII, OIII], CIV

massive star features

- CIV P-Cygni (O stars), HeII (WRs)
- additional metallicity indicators (Rix+2004)

ISM/CGM absorption lines

- CIV, SiII

# COS data!

400 pc  
40 pc!

stellar metallicity  
constraints  
 $Z=0.003-0.008$ ;  
nebular:  $Z=0.005$   
( $\sim Z_{\text{sun}}/3$ )

population synthesis models are uncertain;  
esp. in ionizing flux predictions

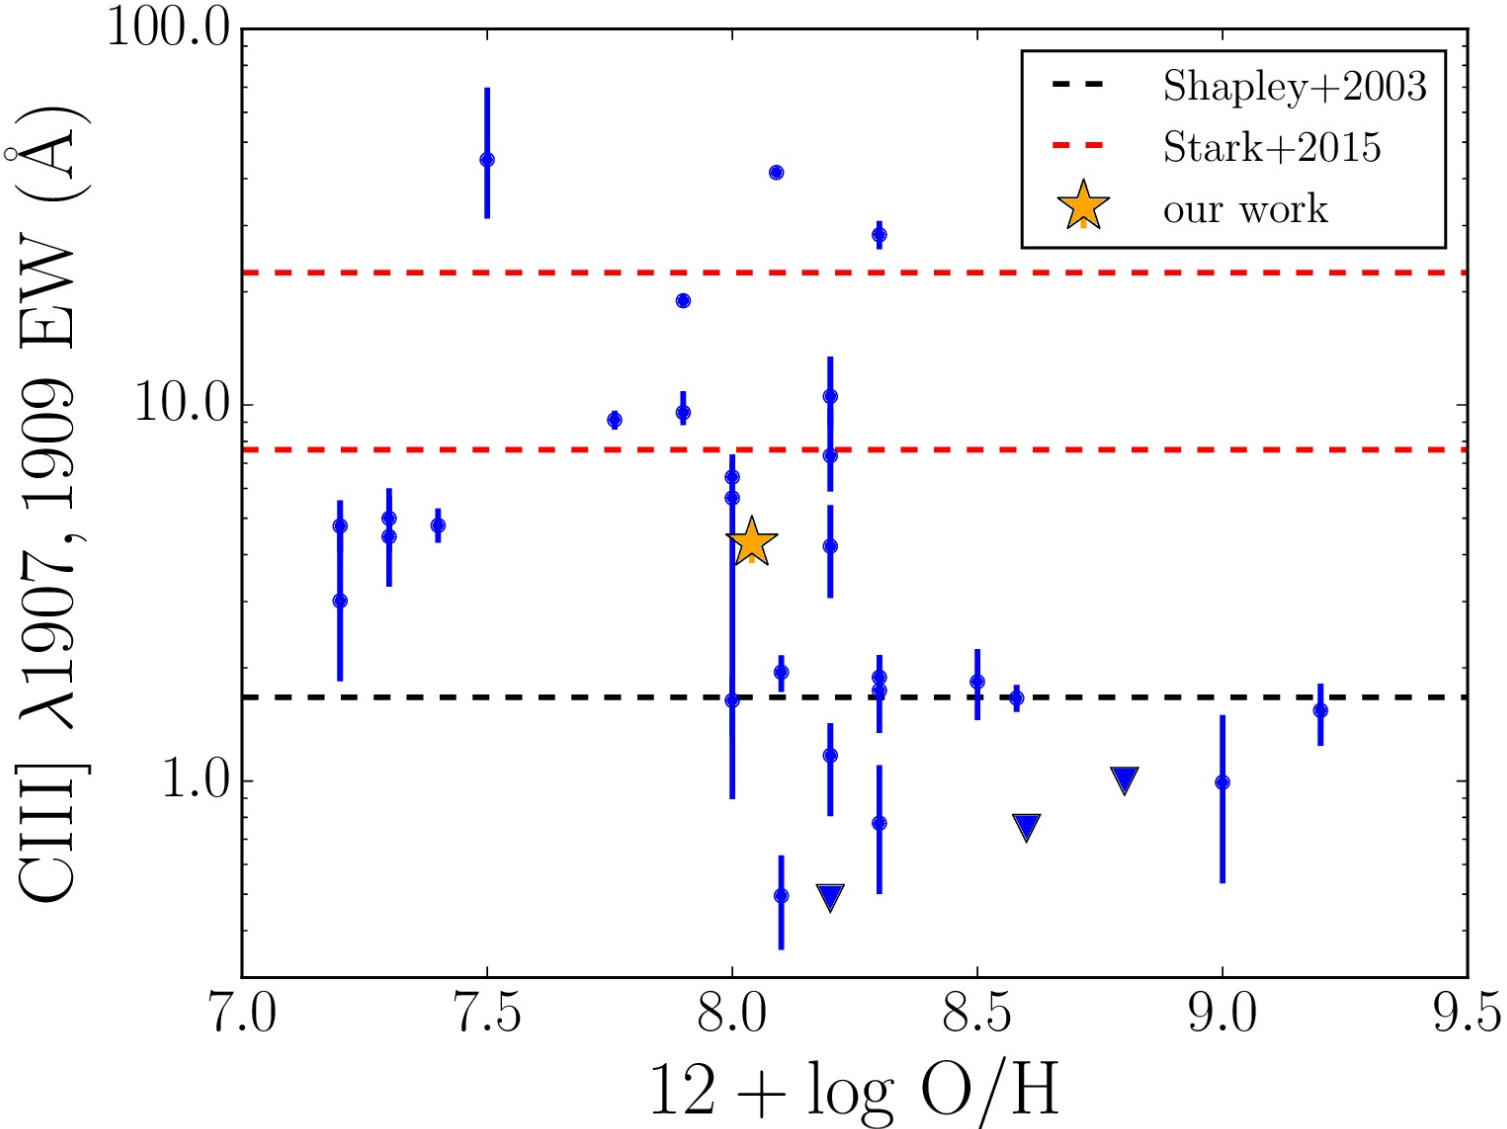

more  
'WR-like'  
stars

decreasing  
metallicity

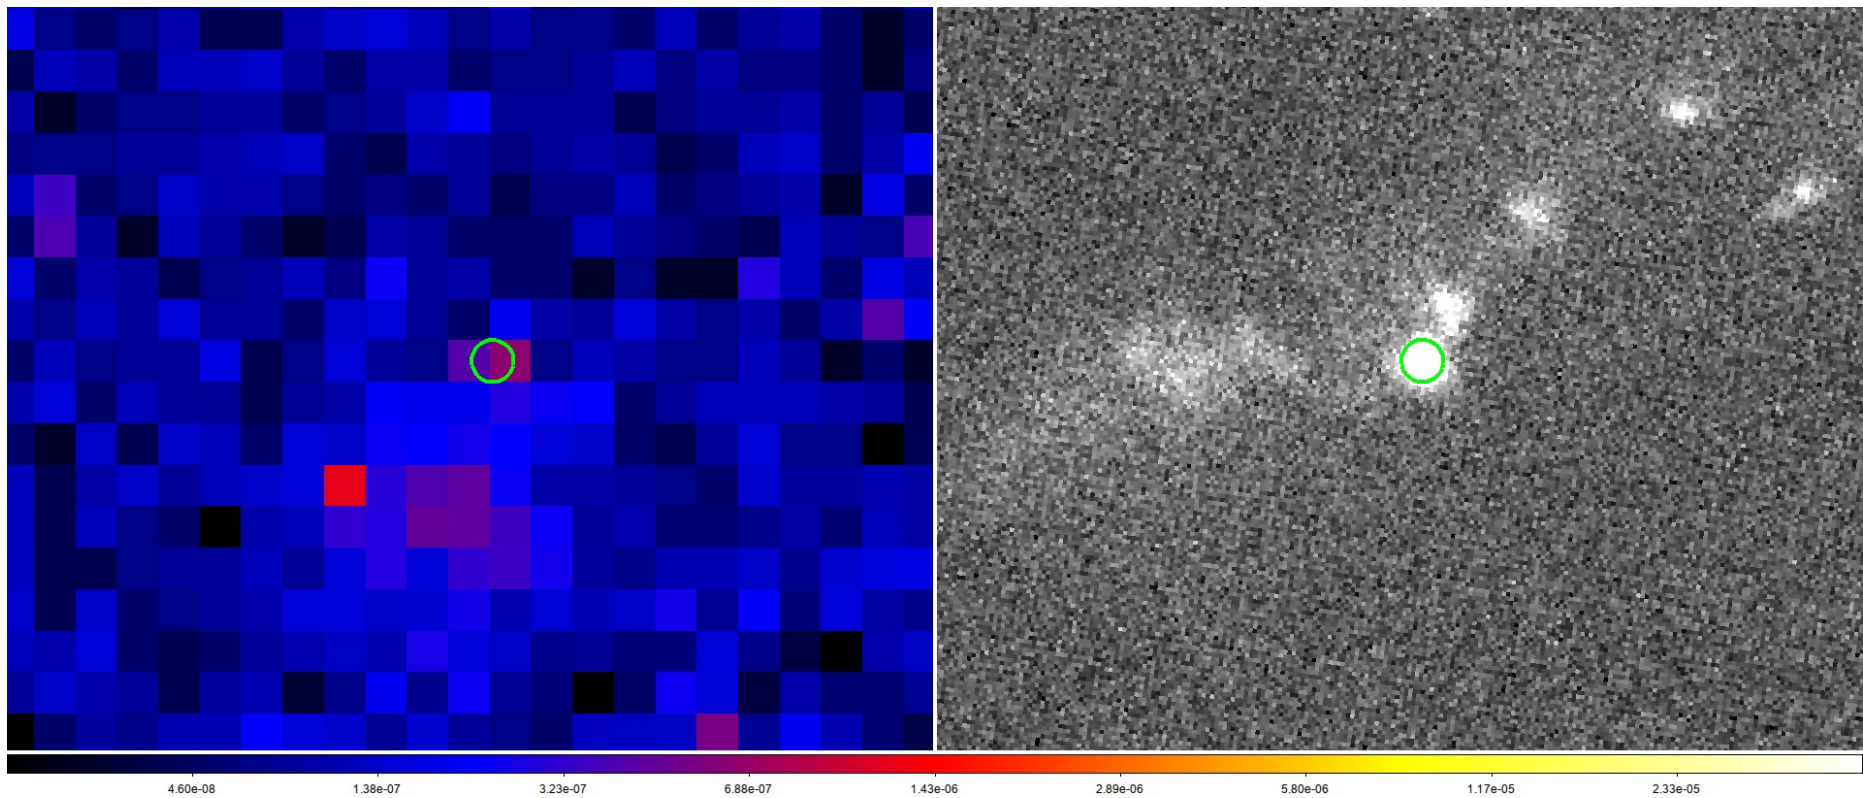

we can anchor these models locally

# multiwavelength data (COS, Chandra, MMT)

empirical templates for JWST

questions?

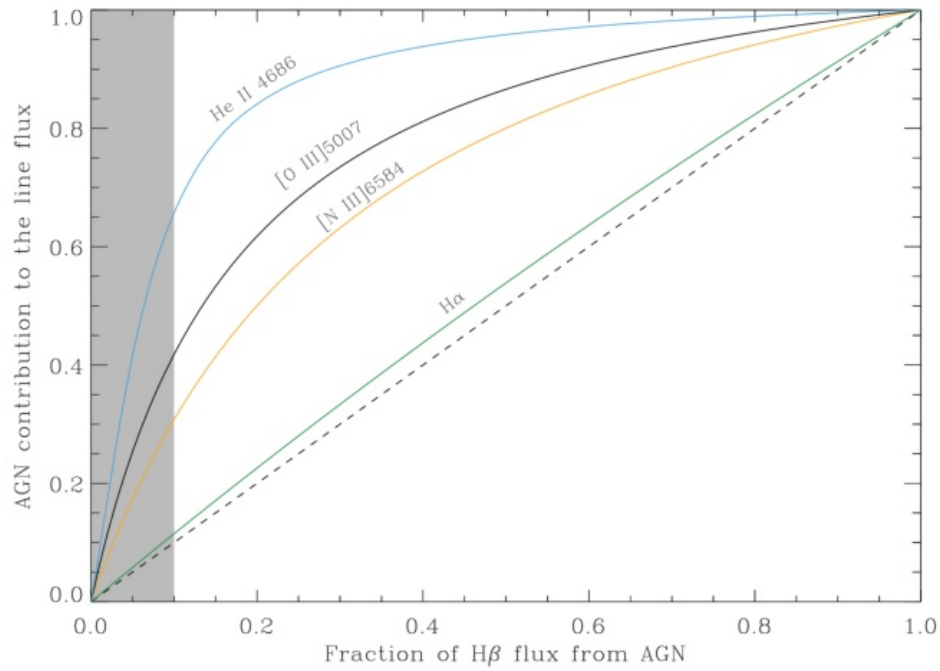

170 ks of Chandra archival data

typical FOS CIV profile

Shirazi & Brinchmann 2012,  
MNRAS 421, 1043
